

House Price Prediction - 1 Page Summary

Student: Kartik Chadda

Project Objective

The objective was to build regression models that predict house prices using features such as area, bedrooms, bathrooms, stories, parking, furnishing status, and facilities like air conditioning and preferred area.

Model Performance

Model	MAE	RMSE	R2 Score
Linear Regression	471,716	581,828	0.912
Random Forest	797,482	968,591	0.755

Key Insights

The strongest signals in the model were: area, airconditioning_yes, bathrooms, stories, bedrooms. Larger area, more bathrooms, air conditioning, preferred area, and better furnishing generally increased predicted price. The Linear Regression was the better model for this dataset because it captured nonlinear relationships better than basic linear regression.

Business Recommendation

A real estate business should not price properties only by area. It should also highlight premium features such as air conditioning, parking, preferred location, bathrooms, and furnishing status because these features strongly influence buyer value and predicted market price.
